A new regret analysis for Adam-type algorithms

Ahmet Alacaoglu 1  Yura Malitsky 1  Panayotis Mertikopoulos 2,3  Volkan Cevher 1

Abstract
In this paper, we focus on a theory-practice gap for Adam and its variants (AMSgrad, AdamNC, etc.). In practice, these algorithms are used with a constant first-order moment parameter $\beta_1$ (typically between 0.9 and 0.99). In theory, regret guarantees for online convex optimization require a rapidly decaying $\beta_1 \to 0$ schedule. We show that this is an artifact of the standard analysis, and we propose a novel framework that allows us to derive optimal, data-dependent regret bounds with a constant $\beta_1$, without further assumptions. We also demonstrate the flexibility of our analysis on a wide range of different algorithms and settings.

1. Introduction

One of the most popular optimization algorithms for training neural networks is ADAM (Kingma & Ba, 2014), which is a variant of the general class of ADAGRAD-type algorithms (Duchi et al., 2011). The main novelty of ADAM is to apply an exponential moving average (EMA) to gradient estimates (first-order) and to element-wise square-of-gradients (second-order), with parameters $\beta_1$ and $\beta_2$, respectively.

In practice, constant $\beta_1$ and $\beta_2$ values are used (the default parameters in PYTORCH and TENSORFLOW, for example, are $\beta_1 = 0.9$ and $\beta_2 = 0.999$). However, the regret analysis in Kingma & Ba (2014) requires $\beta_1 \to 0$ with a linear rate, causing a clear discrepancy between theory and practice.

Recently, Reddi et al. (2018) showed that the analysis of ADAM contains a technical issue. Following this discovery, many variants of ADAM are proposed with regret guarantees (Reddi et al., 2018; Chen & Gu, 2018; Huang et al., 2019). Unfortunately, in all these analyses, the requirement $\beta_1 \to 0$ is inherited and needed to derive the optimal $\mathcal{O}(\sqrt{T})$ regret. In contrast, for favorable practical performance, methods continue to use constant $\beta_1$ in experiments.

One can wonder whether there is an inherent obstacle – in the proposed methods or the setting – which prohibits optimal regret bounds with a constant $\beta_1$?

In this work, we show that this specific discrepancy between the theory and practice is indeed an artifact of the previous analyses. We point out the shortcomings responsible for this artifact, and then introduce a new analysis framework that attains optimal regret bounds with constant $\beta_1$ at no additional cost (and even comes with better constants in the obtained bounds).

Our contributions. In the convex setting, our technique obtains data-dependent $\mathcal{O}(\sqrt{T})$ regret bounds for AMSgrad and ADAMNC (Reddi et al., 2018). Moreover, our technique can also be applied to a strongly convex variant of ADAMNC, known as SADAM (Wang et al., 2020), yielding again data-dependent logarithmic regret with constant $\beta_1$. To the best of our knowledge, these are the first optimal regret bounds with constant $\beta_1$.

Finally, we illustrate the flexibility of our framework by applying it to zeroth-order (bandit) and nonconvex optimization. In the zeroth-order optimization setting, we improve on the current best result which requires $\beta_1 \sim \frac{1}{T}$, and show that a constant $\beta_1$ again suffices. In the non-convex setting, we recover the existing results in the literature, with a simpler proof and slight improvements in the bounds.

It is worth noting that even though our analysis is more flexible and it provides better bounds than prior works, it is not sufficient to explain why nonzero $\beta_1$ helps in practice. This is an interesting question requiring further investigation and is outside the scope of this paper.

1.1. Problem Setup

In online optimization, a loss function $f_t : \mathcal{X} \to \mathbb{R}^d$ is revealed, after a decision vector $x_t \in \mathcal{X}$ is picked by the algorithm. We then minimize the regret defined as

$$R(T) = \sum_{t=1}^{T} f_t(x_t) - \min_{x \in \mathcal{X}} \sum_{t=1}^{T} f_t(x).$$

Our assumptions are summarized below which are the same as in (Reddi et al., 2018).
We note that \( R \) work in Euclidean space \((2019)\), \( N \) \( A \)

2.1. Convex world

Following Reddi et al. (2018), there has been a surge of interest in proposing new variants of \( A \) with good practical properties; to name a few, \( \text{PADAM by Chen \& Gu (2018), ADABOUND and AMSBOUND by Luo et al. (2019); Savarese (2019), NOSTALGIC ADAM by Huang et al. (2019).} \)

As the regret analyses of these methods follow very closely the analysis of Reddi et al. (2018), the resulting bounds inherited the same shortcomings. In particular, in all these algorithms, to achieve \( O(\sqrt{T}) \) regret, one needs either \( \beta_{1t} = \beta_1 \lambda^{t-1} \) or \( \beta_{1t} = \frac{\eta}{t} \). On the other hand, the experimental results reported on these algorithms note that a constant value of \( \beta_1 \) is used in practice in order to obtain better performance.

Similar issues are present in other problem settings. For strongly convex optimization, Wang et al. (2020) proposed the SADAM algorithm as a variant of ADAMNC, which exploits strong convexity to obtain \( O(\log T) \) regret. SADAM was shown to exhibit favorable practical performance in the experimental results of Wang et al. (2020). However, the same discrepancy exists as with previous ADAM variants: a linearly decreasing \( \beta_{1t} \) schedule is required in theory but a constant \( \beta_{1t} = \beta_1 \) is used in practice.

One work that tried to address this issue is that of Fang & Klabjan (2019, Theorem 2), where the authors focused on OCO with strongly convex loss functions and derived an \( O(\sqrt{T}) \) regret bound with a constant value of \( \beta_1 \leq \frac{\mu \alpha}{\sqrt{T}} \), where \( \mu \) is the strong convexity constant and \( \alpha \) is the step size that is set as \( \alpha_1 / \sqrt{T} \). (Fang & Klabjan, 2019, Theorem 2). However, this result is still not satisfactory, since the obtained bound for \( \beta_1 \) is weak: both strong convexity \( \mu \) and the step size \( \alpha_1 / \sqrt{T} \) are small. This does not allow for the standard choices of \( \beta_1 \in (0.9, 0.99) \).

Moreover, a quick look into the proof of Fang & Klabjan (2019, Theorem 2) reveals that the proof in fact follows the same lines as Reddi et al. (2018) with the difference of using the contribution of strong convexity to get rid of the spurious terms that require \( \beta_1 \to 0 \). Therefore, it is not surprising that the theoretical bound for \( \beta_1 \) depends on \( \mu \) and \( \alpha \) and can only take values close to 0. Second, in addition to the standard Assumption 1, Fang & Klabjan (2019) also assumes strong convexity, which is a quite stringent assumption by itself. In contrast, our approach does not follow the lines of Reddi et al. (2018), but is an alternative way that does not encounter the same roadblocks.

2.2. Nonconvex world

A related direction to what we have reviewed in the previous subsection is to analyze ADAM-type algorithms without convexity assumptions. When convexity is removed, the standard setting in which the algorithms are analyzed, is stochastic optimization with a smooth loss function and no constraints (Chen et al., 2019a; Zhou et al., 2018; Zou et al., 2019). As a result, these algorithms, compared to the convex counterparts, do not perform projections in the update step of \( x_{t+1} \) (cf., Algorithm 1).

In addition to smoothness, bounded gradients are assumed, which is also restrictive, as many nonconvex functions do

---

**Assumption 1.**

- \( \mathcal{X} \subset \mathbb{R}^d \) is a compact convex set.
- \( f_t: \mathcal{X} \to \mathbb{R} \) is a convex lsc function, \( g_t \in \partial f_t(x_t) \).
- \( D = \max_{x,y \in \mathcal{X}} \| x - y \|_{\infty}, G = \max_t \| g_t \|_{\infty} \).

1.2. Preliminaries

We work in Euclidean space \( \mathbb{R}^d \) with inner product \( \langle \cdot, \cdot \rangle \). For vectors \( a, b \in \mathbb{R}^d \) all standard operations \( ab, a^2, a/b, a^{1/2}, 1/a, \max \{a, b\} \) are supposed to be coordinate-wise.

A vector \( a_t \in \mathbb{R}^d \), we denote its \( i \)-th coordinate by \( a_{t,i} \). We denote the vector of all-ones as \( 1 \). We use \( \text{diag}(a) \) to denote a \( d \times d \) matrix which has \( a \) in its diagonal, and the rest of its elements are 0. For \( v_i > 0, \forall i = 1, \ldots, d \), we define a weighted norm

\[
\| x \|^p_v := \langle x, (\text{diag } v)x \rangle
\]

and a weighted projection operator onto \( \mathcal{X} \)

\[
P^v_{\mathcal{X}}(x) = \arg \min_{y \in \mathcal{X}} \| y - x \|^2_v.
\]

We note that \( \forall x, y \in \mathbb{R}^d, P^v_{\mathcal{X}} \) is nonexpansive, that is

\[
\| P^v_{\mathcal{X}}(y) - P^v_{\mathcal{X}}(x) \|_v \leq \| y - x \|_v.
\]

2. Related work

2.1. Convex world

In the setting of online convex optimization (OCO), Assumption 1 is standard (Hazan et al., 2016; Duchi et al., 2011). It allows us to consider nonsmooth stochastic minimization (though we are not limited to this setting), and even allows for adversarial loss functions.

The algorithms AMSGRAD and ADAMNC were proposed by Reddi et al. (2018) to fix the issue in the original proof of ADAM (Kingma & Ba, 2014). However, as the proof template of Reddi et al. (2018) follows very closely the proof of Kingma & Ba (2014), the requirement for \( \beta_1 \to 0 \) remains in all the regret guarantees of these algorithms. In particular, as noted by Reddi et al. (2018, Corollary 1, 2), a schedule of \( \beta_{1t} = \beta_1 \lambda^{t-1} \) is needed for obtaining optimal regret. Reddi et al. (2018) also noted that regret bounds of the same order can be obtained by setting \( \beta_{1t} = \beta_1 / t \). On the other hand, in the numerical experiments, a constant value \( \beta_{1t} = \beta_1 \) is used consistent with the huge literature following Kingma & Ba (2014).

Following Reddi et al. (2018), there has been a surge of interest in proposing new variants of ADAM with good practical properties; to name a few, PADAM by Chen & Gu (2018), ADABOUND and A MSBOUND by Luo et al. (2019); Savarese (2019), NOSTALGIC ADAM by Huang et al. (2019). As the
not satisfy this property. Indeed, one can show that it is equivalent to the Lipschitz continuity of the function (not its gradient)! Under these assumptions, the standard results bound the minimum gradient norm across all iterations.

An interesting phenomenon in this line of work is that a constant $\beta_1 < 1$ is permitted for the theoretical results, which may seem like weakening our claims. However, it is worth noting that these results do not imply any guarantee for regret in OCO setting.

Indeed, adding the convexity assumption to the setting of unconstrained, smooth stochastic optimization, would only help obtaining a gradient norm bound in the averaged iterate, rather than the minimum across all iterations. However, this bound does not imply any guarantee in the objective value, unless more stringent Polyak-Lojasiewicz or strong convexity requirements are added in the mix.

Moreover, in the OCO setting that we analyze, loss functions are nonsmooth, and there exists a constraint onto which a projection is performed in the $x_{t+1}$ step (cf. Algorithm 1). Finally, online optimization includes stochastic optimization as a special case. Given the difference of assumptions, the analyses in (Chen et al., 2019a; Zhou et al., 2018; Zou et al., 2019) indeed do not help obtaining any regret guarantee for standard OCO.

A good example demonstrating this difference on the set of assumptions is the work (Chen et al., 2019b). In this paper, a variant of AMSGRAD is proposed for zeroth order optimization and it is analyzed in the convex and nonconvex settings. Consistent with the previous literature in both, convergence result for the nonconvex setting allows a constant $\beta_1 < 1$ (Chen et al., 2019b, Theorem 1). However, the result in the convex setting requires a decreasing schedule such that $\beta_{1t} = \frac{\beta_1}{T}$ (Chen et al., 2019b, Proposition 4).

As we highlighted above, the analyses in convex/nonconvex settings follow different paths and the results or techniques are not transferrable to each other. Thus, our main aim in this paper is to bridge the gap in the understanding of regret analysis for OCO and propose a new analytic framework. As we see in the sequel, our analysis not only gives the first results in OCO setting, it is also general enough to apply to the aforementioned nonconvex optimization case and recover similar results as the existing ones.

3. Main results

3.1. Dissection of the standard analysis

We start by describing the shortcoming of the previous approaches in (Reddi et al., 2018; Wang et al., 2020) and, then explain the mechanism that allows us to obtain regret bounds with constant $\beta_1$. In this subsection, for full generality, we assume that the update for $m_t$ is not done with $\beta_1$, but with $\beta_{1t}$, as in (Reddi et al., 2018; Kingma & Ba, 2014): $m_t = \beta_{1t}m_{t-1} + (1 - \beta_{1t})g_t$. (4)

The standard way to analyze Adam-type algorithms is to start by the nonexpansiveness property (3) and to write

$$\|x_{t+1} - x\|_{\theta_t}^2 \leq \|x_t - x\|_{\theta_t}^2 - 2\alpha_t(m_t, x_t - x) + \alpha_t^2\|m_t\|_{\theta_t^{-1}}^2.$$  

Then using (4), one can deduce

$$(1 - \beta_{1t})(g_t, x_t - x) \leq -\beta_{1t}\langle m_{t-1}, x_t - x \rangle$$  

$$+ \frac{\alpha_t}{2}\|m_t\|_{\theta_t^{-1}}^2 + \frac{1}{2\alpha_t}(\|x_t - x\|_{\theta_t}^2 - \|x_{t+1} - x\|_{\theta_t^{-1}}^2).$$

Let us analyze the above inequality. Its left-hand side is exactly what we want to bound, since by convexity $R(T) \leq \sum_{t=1}^T (g_t, x_t - x)$. The last two terms in the right-hand side are easy to analyze, all of them can be bounded in a standard way using just definitions of $\theta_t$, $m_t$, and $\alpha_t$.

What can we do with the term $-\beta_{1t}\langle m_{t-1}, x_t - x \rangle$? Analysis in (Reddi et al., 2018) bounds it with Young’s inequality

$$-\beta_{1t}\langle m_{t-1}, x_t - x \rangle \leq \frac{\beta_{1t}}{2\alpha_t}\|x_t - x\|_{\theta_t}^2$$  

$$+ \frac{\beta_{1t}\alpha_t}{2}\|m_{t-1}\|_{\theta_t^{-1}}^2.$$  

The term $\frac{\beta_{1t}}{2\alpha_t}\|x_t - x\|_{\theta_t}^2$ is precisely what leads to the second term in the regret bound in (Reddi et al., 2018, Theorem 4). Since $\alpha_t = \frac{1}{\sqrt{t}}$, one must require $\beta_{1t} \rightarrow 0$.

Note that the update for $x_{t+1}$ has a projection. This is important, since otherwise a solution must lie in the interior of $\mathcal{X}$, which is not the case in general for problems with a compact domain. However, let us assume for a moment that the update for $x_{t+1}$ does not have any projection. In this simplified setting, applying the following trick will work.

Recall that $x_t = x_{t-1} - \alpha_{t-1} \hat{v}_{t-1}^{1/2}m_{t-1}$, or equivalently $m_{t-1} = \frac{1}{\alpha_{t-1}}\hat{v}_{t-1}^{1/2}(x_{t-1} - x_t)$. Plugging it into the error term $\langle m_{t-1}, x_t - x \rangle$ yields

$$-\langle m_{t-1}, x_t - x \rangle = \frac{1}{\alpha_{t-1}}\hat{v}_{t-1}^{1/2}(x_{t-1} - x_t), x_t - x)$$  

$$= \frac{1}{2\alpha_{t-1}}\left[\|x_t - x_{t-1}\|_{\hat{v}_{t-1}}^2 + \|x_t - x\|_{\hat{v}_{t-1}}^2 - \|x_{t-1} - x\|_{\hat{v}_{t-1}}^2\right]$$  

$$\leq \frac{1}{2}\alpha_{t-1}\|m_{t-1}\|_{\hat{v}_{t-1}}^2 + \frac{1}{2}\|x_t - x\|_{\hat{v}_{t-1}}^2/\alpha_{t-1}$$  

$$- \|x_{t-1} - x\|_{\hat{v}_{t-1}}^2/\alpha_{t-1}.$$
where the second equality follows from the Cosine Law and the first inequality is from $x_t - x_{t-1} = -\alpha_{t-1} \tilde{v}_{t-1}^{-1/2} m_{t-1}$ and $\tilde{v}_t^{-1/2} / \alpha_t \geq \tilde{v}_{t-1}^{-1/2} / \alpha_{t-1}$. We now compare this bound with the previous one. The term $\alpha_{t-1} \|m_{t-1}\|_2^2 \tilde{v}_{t-1}^{-1/2}$, as we already observed, is good for summation. And other two terms are going to cancel after summation over $t$. Hence, it is easy to finish the analysis to conclude $O(\sqrt{T})$ regret with a fixed $\beta_{1t} = \beta_1$.

Unfortunately, the update for $x_{t+1}$ does have a projection, without it the assumption for the domain to be bounded is very restrictive. This prevents us from using the above trick. Its message, however, is that it is feasible to expect a good bound even with a fixed $\beta_{1t}$, and under the same assumptions on the problem setting.

For having a more general technique to handle $\beta_1$, we will take a different route in the very beginning — we will analyze the term $\langle g_t, x_t - x \rangle$ in a completely different way, without resorting to any crude inequality as in (Reddi et al., 2018). Basically, this idea can be applied to any framework with a similar update for the moment $m_t$.

### 3.2. A key lemma

As we understood above, the presence of the projection complicates handling $\langle m_{t-1}, x_t - x \rangle$. A high level explanation for the cause of the issue is that the standard analysis does not leave much flexibility, since it uses nonexpansiveness in the very beginning.

**Lemma 1.** Under the definition

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t,$$

it follows that

$$\langle g_t, x_t - x \rangle = \langle m_{t-1}, x_{t-1} - x \rangle - \frac{\beta_1}{1 - \beta_1} \langle m_{t-1}, x_t - x_{t-1} \rangle + \frac{1}{1 - \beta_1} \left( \langle m_t, x_t - x \rangle - \langle m_{t-1}, x_{t-1} - x \rangle \right).$$

The main message of Lemma 1 is that the decomposition of $m_t$, in the second part of the analysis in Section 3.1 is now done before using nonexpansiveness, therefore there would be no need for using Young’s inequality which is the main shortcoming of the previous analysis.

Upon inspection on the bound, it is now easy to see that the last two terms will telescope. The second term can be shown to be of the order $\alpha_t \|m_t\|_2^2 \tilde{v}_t^{-1/2}$, and as we have seen before, summing this term will give $O(\sqrt{T})$. To see that the first term is also benign, a high level explanation is to notice that $m_{t-1}$ is the gradient estimate used in the update $x_t = x_{t-1} - \alpha_{t-1} \tilde{v}_{t-1}^{-1/2} m_{t-1}$, therefore it can be analyzed in the classical way.

We proceed to illustrate the flexibility of the new analysis on three popular ADAM variants that are proven to converge.

### 3.3. AMSGRAD

AMSGrad is proposed by (Reddi et al., 2018) as a fix to ADAM. The algorithm incorporates an extra step to enforce monotonicity of second moment estimator $\hat{v}_t$.

**Algorithm 1 AMSGRAD (Reddi et al., 2018)**

```
1: Input: $x_1 \in \mathcal{X}$, $\alpha_t = \frac{\sqrt{T}}{\sqrt{t}}$, $\alpha > 0$, $\beta_1 < 1$, $\beta_2 < 1$, $m_0 = v_0 = 0$, $\hat{v}_0 = \varepsilon 1$, $\varepsilon \geq 0$
2: for $t = 1, 2, \ldots$ do
3: $g_t \in \partial f_t(x_t)$
4: $m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t$
5: $v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2$
6: $\hat{v}_t = \max(\hat{v}_{t-1}, v_t)$
7: $x_{t+1} = \text{Proj}_{\hat{v}_t^{1/2}} (x_t - \alpha_t \hat{v}_t^{-1/2} m_t)$
8: end for
```

The regret bound for this algorithm in (Reddi et al., 2018, Theorem 4, Corollary 1) requires a decreasing $\beta_1$ at least at the order of $1/t$ to obtain $O(\sqrt{T})$ worst case regret. Moreover, it is easy to see that a constant $\beta_1$ results in $O(T\sqrt{T})$ worst case regret in (Reddi et al., 2018, Theorem 4).

We now present the following theorem which shows that the same $O(\sqrt{T})$ can be obtained by AMSGRAD under the same structural assumptions as (Reddi et al., 2018).

**Theorem 1.** Under Assumption 1, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \frac{\beta_1^2}{\beta_2} < 1$, and $\varepsilon > 0$, AMSGrad achieves the regret

$$R(T) \leq \frac{D^2 \sqrt{T}}{2\alpha(1 - \beta_1)} \sum_{i=1}^d \hat{v}_{T,i}^{1/2} + \frac{\alpha \sqrt{1 + \log T}}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{i=1}^d \sum_{t=1}^T g_{t,i}^2. \quad (5)$$

We would like to note that our bound for $R(T)$ is also better than the one in (Reddi et al., 2018) in term of constants. We have only two terms in contrast to three in (Reddi et al., 2018) and each of them is strictly smaller than their counterparts in (Reddi et al., 2018). The reason is that we used i) new way of decomposition $\langle g_t, x_t - x \rangle$ as in Lemma 1, ii) wider admissible range for $\beta_1, \beta_2$, iii) more refined estimates for analyzing terms. For example, the standard analysis to estimate $\|m_t\|_2^2 \hat{v}_t^{-1/2}$ uses several Cauchy-Schwarz inequalities. We instead give a better bound by applying generalized Hölder inequality (Beckenbach & Bellman, 1961).
Another observation is that having a constant $\beta_1$ explicitly improves the last term in the regret bound. If one uses a non-decreasing $\beta_1$, instead of constant $\beta_1$, then this term will have an additional multiple of $1/(1-\beta_1)^2$. Given that in general one chooses $\beta_1$ close to 1, this factor is significant.

Remark 1. Notice that Theorem 1 requires $\varepsilon > 0$ in order to have the weighted projection operator in (2) well-defined. Such a requirement is common in the literature for theoretical analysis, see (Duchi et al., 2011, Theorem 5). In practice, however, one can set $\varepsilon = 0$.

Proof sketch. We sum $\langle g_t, x_t - x \rangle$ from Lemma 1 over $t$, use $m_0 = 0$ to get

$$
\sum_{t=1}^{T} \langle g_t, x_t - x \rangle \leq \sum_{t=1}^{T} \langle m_t, x_t - x \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle + \frac{\beta_1}{1 - \beta_1} \langle m_T, x_T - x \rangle.
$$

By Hölder inequality, we can show that

$$
S_2 \leq \sum_{t=1}^{T-1} \alpha_t \|m_t\|_{\delta_t^{-1/2}}^2.
$$

By using the fact that $\hat{v}_{t,i} \geq \hat{v}_{t-1,i}$, and the same estimation as deriving $S_2$,

$$
S_1 \leq \frac{D^2}{2\alpha_T} \sum_{i=1}^{d} \hat{v}_{t,i}^{1/2} + \frac{T}{2} \alpha \|m_t\|_{\delta_t^{-1/2}}^2.
$$

By Hölder and Young’s inequalities, we can bound $S_3$ as

$$
S_3 \leq \alpha_T \|m_T\|_{\delta_t^{-1/2}}^2 + \frac{D^2}{4\alpha_T} \sum_{i=1}^{d} \hat{v}_{t,i}^{1/2}.
$$

Lastly, we see that $\alpha_t \|m_t\|_{\delta_t^{-1/2}}^2$ is common in all these terms and it is well known that this term is good for summation

$$
\sum_{t=1}^{T} \alpha_t \|m_t\|_{\delta_t^{-1/2}}^2 \leq \frac{(1-\beta_1)\alpha\sqrt{1+\log T}}{\sqrt{(1-\beta_2)(1-\gamma)}} \sum_{i=1}^{T} \|g_{t,i}\|_{\delta_t^{-1/2}}^2.
$$

Combining the terms gives the final bound.

Finally, if we are interested in the worst case scenario, it is clear that Theorem 1 gives regret $R(T) = O(\sqrt{\log(T)}T)$.

A quick look into the calculations yields that if one uses the worst case bound $g_{t,i} \leq G$, then the bound will not include a logarithmic term. However, then the data-dependence of the bound will be lost. It is not clear if one can obtain a data-dependent $O(\sqrt{T})$ regret bound. In the following corollary, we give a partial answer to this question.

Corollary 1. Under Assumption 1, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \beta_2^2 < 1$, and $\varepsilon > 0$, AMSGRAD achieves the regret

$$
R(T) \leq \frac{D^2\sqrt{T}}{2\alpha(1-\beta_1)} \sum_{i=1}^{d} \hat{v}_{T,i}^{1/2} + \frac{\alpha\sqrt{G}}{\sqrt{1-\beta_2(1-\gamma)}} \sum_{i=1}^{d} \sqrt{\sum_{t=1}^{T} |g_{t,i}|}.
$$

We remark that even though this bound does not contain a $\log(T)$ term, thus better in the worst-case, its data-dependence is actually worse than the standard bound. Standard bound contains $g_{t,i}$ whereas bound above contains $|g_{t,i}|$. Therefore, when the values $g_{t,i}$ are very small, the bound with $\log T$ can be better. We leave it as an open question to have a $\sqrt{T}$ bound with the same data-dependence as the original bound.

3.4. ADAMNC

Another variant that is proposed by Reddi et al. (2018) as a fix to ADAM is ADAMNC which features an increasing schedule for $\beta_2t$. In particular, one sets $\beta_{2t} = 1 - \frac{1}{t}$ in

$$
v_t = \beta_{2t}v_{t-1} + (1 - \beta_{2t})g_{t,i},
$$

that results in the following expression for $v_t$

$$
v_t = \frac{1}{t} \sum_{j=1}^{t} g_j^2,
$$

which is a reminiscent of ADAGRAD (Duchi et al., 2011).

In fact, to ensure that $P_{x_t^{1/2}}$ is well-defined, one needs to consider the more general update $v_t = \frac{1}{t} \left(\sum_{j=1}^{t} g_j^2 + \varepsilon 1\right)$ similar to the previous case with AMSGRAD.

ADAMNC is analyzed in (Reddi et al., 2018, Theorem 5, Corollary 2) and similar to AMSGRAD it has been shown to exhibit $O(\sqrt{T})$ worst case regret only when $\beta_1$ decreases to 0. We show in the following theorem that the same regret can be achieved with a constant $\beta_1$.

Theorem 2. Under Assumption 1, $\beta_1 < 1$, and $\varepsilon > 0$, ADAMNC achieves the regret

$$
R(T) \leq \frac{D^2\sqrt{T}}{2\alpha(1-\beta_1)} \sum_{i=1}^{d} \hat{v}_{T,i}^{1/2} + \frac{2\alpha}{1 - \beta_1} \sum_{i=1}^{d} \sqrt{\sum_{t=1}^{T} g_{t,i}^2}.
$$
A new regret analysis for Adam-type algorithms

Algorithm 2 ADAMNC (Reddi et al., 2018)

1: **Input:** $x_1 \in X$, $\alpha_t = \frac{\alpha}{\sqrt{t}}$, $\alpha > 0$, $\beta_1 < 1$, $\varepsilon \geq 0$, $m_0 = 0$.
2: for $t = 1, 2 \ldots$ do
3:     $g_t \in \partial f_t(x_t)$
4:     $m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t$
5:     $v_t = \frac{1}{\eta} \left( \sum_{j=1}^{t-1} g_j^2 + \varepsilon I \right)$
6:     $x_{t+1} = P^{v_{t,1/2}}_\alpha (x_t - \alpha_t v_t^{-1/2} m_t)$
7: end for

We skip the proof sketch of this theorem as it will have the same steps as AMSGRAD, just different estimation for $\alpha_t \| m_t \|_{v_t^{-1/2}}^2$, due to different $v_t$.

The full proof is given in the appendix.

Compared with the bound from (Reddi et al., 2018, Corollary 2), we see again that constant $\beta_1$ not only removes the middle term of (Reddi et al., 2018, Corollary 2) but improves the last term of the bound by a factor of $(1 - \beta_1)^2$.

3.5. SADAM

It is known that ADAGRAD can obtain logarithmic regret (Duchi et al., 2010), when the loss functions satisfy $\mu$-strong convexity, defined as $f(x) \geq f(y) + \langle g, x - y \rangle + \frac{\mu}{2} \|y - x\|^2$, for all $y, x \in X$ and $g \in \partial f(y)$.

A variant of ADAMNC for this setting is proposed in (Wang et al., 2020, Theorem 1) and shown to obtain logarithmic regret, with the assumption that $\beta_1$ decreases linearly to 0.

Algorithm 3 SADAM (Wang et al., 2020)

1: **Input:** $x_1 \in X$, $\alpha_t = \frac{\alpha}{t}$, $\alpha > 0$, $\beta_1 < 1$, $m_0 = 0$, $\varepsilon \geq 0$, $\beta_2 = 1 - 1/t$.
2: for $t = 1, 2 \ldots$ do
3:     $g_t \in \partial f_t(x_t)$
4:     $m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t$
5:     $v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2$
6:     $\hat{v}_t = v_t + \frac{\varepsilon}{\beta_2}$
7:     $x_{t+1} = P^{\hat{v}_{t,1/2}}_\alpha (x_t - \alpha_t \hat{v}_t^{-1} m_t)$
8: end for

Similar to AMSGRAD and ADAMNC, our new technique applies to SADAM to show logarithmic regret with a constant $\beta_1$ under the same assumptions as (Wang et al., 2020).

**Theorem 3.** Let Assumption 1 hold and $f_t$ be $\mu$-strongly convex, $\forall t$. Then, if $\beta_1 < 1$, $\varepsilon > 0$, and $\alpha \geq \frac{G^2}{\mu}$, SADAM achieves

$$R(T) \leq \frac{\beta_1 dGD}{1 - \beta_1} + \alpha \left( \frac{1}{1 - \beta_1} \sum_{t=1}^{T} g_t^2 + 1 \right) \log \left( \frac{T}{\varepsilon} \right).$$

Consistent with the standard literature of OGD (Hazan et al., 2007), to obtain the logarithmic regret, first step size $\alpha$ has a lower bound that depends on strong convexity constant $\mu$. Compared with the requirement of (Wang et al., 2020) for $\alpha \geq \frac{\mu}{\mu(1 - \beta_1)^2}$, our requirement is strictly milder as $1 - \beta_1 \leq 1$ and in practice since $\beta_1$ is near 1, it is much milder. We also remark that our bound is again strictly better than (Wang et al., 2020). Consistent with our previous results, we remove a factor of $\frac{1}{(1 - \beta_1)^2}$ from the last term of the bound, compared to (Wang et al., 2020, Theorem 1).

We include the proof sketch to highlight how strong convexity helps in the analysis.

**Proof sketch.** We will start the same as proof sketch of Theorem 1 to get

$$\sum_{t=1}^{T} (g_t, x_t - x) \leq S_1 + \frac{\beta_1}{1 - \beta_1} S_2 + \frac{\beta_1}{1 - \beta_1} S_3,$$

with the definitions of $S_1$, $S_2$, $S_3$ from the proof sketch of Theorem 1.

Now, due to strong convexity, one gets an improved estimate for the left-hand side,

$$\langle g_t, x_t - x \rangle \geq f_t(x_t) - f_t(x) + \frac{\mu}{2} \|x_t - x\|^2,$$

resulting in

$$R(T) \leq S_1 + \frac{\beta_1}{1 - \beta_1} S_2 + \frac{\beta_1}{1 - \beta_1} S_3 - \sum_{t=1}^{T} \frac{\mu}{2} \|x_t - x\|^2. \quad (7)$$

Similar as before, we note the bound for $S_2$ as

$$S_2 \leq \sum_{t=1}^{T-1} \alpha_t \|m_t\|_{\hat{v}_t^{-1/2}}^2. \quad (8)$$

For $S_1$, one does not finish the estimation as before, but keep some terms that will be gotten rid of using strong convexity, and use the same estimation as $S_2$ to obtain

$$S_1 \leq \sum_{t=1}^{T} \sum_{i=1}^{d} \left( \frac{\hat{v}_{t,i}}{2 \alpha_t} \right) (x_{t,i} - x_i)^2 + \sum_{t=1}^{T} \frac{\alpha_t}{2} \|m_t\|_{\hat{v}_t^{-1/2}}^2. \quad (9)$$

As strong convexity gives more flexibility in the analysis, one can select $\alpha_t = \frac{\alpha}{t}$, resulting in an improved bound

$$\sum_{t=1}^{T} \frac{\alpha_t}{2} \|m_t\|_{\hat{v}_t^{-1/2}}^2 \leq \sum_{t=1}^{T} \log \left( \frac{T}{\varepsilon} \right). \quad (10)$$
We note that this stochastic optimization setting corresponds to the setting of (Chen et al., 2019b), where two cases are analyzed by Chen et al. (2019b): convex and nonconvex settings.

The algorithm ZO-AdaMM (Chen et al., 2019b) is similar to a zeroth order variant of AMSG, which required decreasing $\beta_1$ in the convex case (Chen et al., 2019b, Proposition 4), and we show that the same guarantees can be obtained with constant $\beta_1$. Second, we show how to recover the known guarantees in the nonconvex setting, with small improvements. Finally, we extend our analysis to show that it allows any non-increasing variable $\beta_t$.

### 4. Extensions

In this section, we further demonstrate the applicability of our analytic framework in different settings. First, we focus on the recently proposed zeroth-order version of AMSGRAD which required decreasing $\beta_1$ in the convex case (Chen et al., 2019b, Proposition 4), and we show that the same guarantees can be obtained with constant $\beta_1$. Second, we show how to recover the known guarantees in the nonconvex setting, with small improvements. Finally, we extend our analysis to show that it allows any non-increasing variable $\beta_t$ schedule.

#### 4.1. Zeroth order ADAM

We first recall the setting of (Chen et al., 2019b), where a zeroth order variant of AMSGRAD is proposed. The problem is

$$x_\ast \in \arg \min_{x \in \mathcal{X}} f(x) := \mathbb{E}_\xi [f(x; \xi)].$$

(11)

We note that this stochastic optimization setting corresponds to a special case of general OCO, with independent and identically distributed loss functions $f(x; \xi)$, indexed by $\xi$.

The algorithm ZO-AdaMM (Chen et al., 2019b) is similar to AMSGRAD applied with a zeroth order gradient estimator $\hat{g}_t$, instead of regular gradient $g_t$. The gradient estimator is computed by

$$\hat{g}_t = (d/\mu) \left[ f(x_t + \mu u; \xi_t) - f(x_t; \xi_t) \right] u,$$

(12)

where $\xi_t$ is the sample selected at iteration $t$, $u$ is a random vector drawn with uniform distribution from the sphere of a unit ball and $\mu$ is a sampling radius, or smoothing parameter.

The benefit of this gradient estimator is that it is an unbiased estimator of the randomized smoothed version of $f$, i.e.,

$$f_{\mu}(x) = \mathbb{E}_{u \sim \mathcal{U}} [f(x + \mu u)].$$

(13)

From standard results in the zeroth-order optimization literature, it follows that $\mathbb{E}_u [\hat{g}_t] = \nabla f_{\mu}(x_t, \xi_t) = \nabla f_{\mu,\xi_t}(x_t)$.

Moreover, for $L_c$-Lipschitz $f$ and any $x \in \mathcal{X}$, we also have $\|f_{\mu}(x) - f(x)\| \leq \mu L_c$.

Two cases are analyzed by Chen et al. (2019b): convex $f$ and nonconvex $f$. The authors proved guarantees with constant $\beta_1$ for nonconvex $f$ (Chen et al., 2019b, Proposition 2).

However, surprisingly, their result for convex $f$ requires $\beta_{1t} = \frac{\beta_1}{t}$ (Chen et al., 2019b, Proposition 4).

We identify that this discrepancy is due to the fact that their proof follows the same path as the standard regret analysis of Reddi et al. (2018). We give below a simple corollary of our technique showing that the same guarantees for convex $f$ can be obtained with constant $\beta_1$.

**Proposition 1.** Assume that $f$ is convex, $L$-smooth, and $L_c$-Lipschitz, $\mathcal{X}$ is compact with diameter $D$. Then ZO-AdaMM with $\beta_1, \beta_2 < 1$, $\gamma = \frac{\beta_2}{\beta_1} < 1$ achieves

$$\mathbb{E} \left[ \sum_{t=1}^T f_{t,\mu}(x_t) - f_t,\mu(x_*) \right] \leq$$

$$\frac{D^2 \sqrt{T}}{2 \alpha (1 - \beta_1)} \sum_{t=1}^d \mathbb{E} \left[ \beta_{1t}^{1/2} \right] + \frac{\alpha \sqrt{1 + \log T}}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{t=1}^d \sum_{i=1}^d \mathbb{E} [g_{t,i}^2].$$

To finish the arguments, one can use standard bounds in zeroth order optimization, as in Chen et al. (2019b). Compared with Chen et al. (2019b, Proposition 4), the same remarks hold as for AMSGRAD. Not only our result allows constant $\beta_1$, but it also comes with better constants.

#### 4.2. Nonconvex AMSGRAD

In this section, we focus on the nonconvex, unconstrained, smooth, stochastic optimization setting:

$$\min_{x \in \mathbb{R}^d} f(x) := \mathbb{E}_\xi [f(x; \xi)].$$

More concretely, in this subsection we are working under the following assumption.

**Assumption 2.**

- $f: \mathbb{R}^d \to \mathbb{R}$ is $L$-smooth, $G = \max_t \|\nabla f(x_t)\|_\infty$
- $f_t(x) = f(x, \xi_t)$
- $x_\ast \in \arg \min_{x \in \mathbb{R}^d} f(x)$ exists.

This is the only setting where theoretical guarantees with constant $\beta_1$ are known in the literature. We show in this section that our new analysis framework is not restricted to convex case, but it is flexible enough to also cover this case.

We provide an alternative proof to those given in (Chen et al., 2019a; Zhou et al., 2018). Specifically, both proofs in (Chen et al., 2019a; Zhou et al., 2018) exploits the fact that, as $\mathcal{X} = \mathbb{R}^d$, there is no projection step in AMSGRAD. To handle first-order moment, these papers define an auxiliary iterate $z_t = x_t + \frac{\beta_1}{\beta_t}(x_t - x_{t-1})$, and invoke smoothness with $z_{t+1}$ and $z_t$. 

- It is now easy to see that the negative term in (7), when first step size $\alpha$ is selected properly, can be used to remove the first term in the bound of (9).
- It only remains to use Hölder inequality on $S_3$, combine the estimates and use (10) to get the final bound.
We give a different and simpler proof using our new analysis, without defining \( z_t \). In terms of guarantees, we recover the same rates, with slightly better constants.

**Theorem 4.** Under Assumption 2, \( \beta_1 < 1, \beta_2 < 1, \) and \( \gamma = \frac{\alpha^2}{\beta_2} < 1 \) AMSGRAD achieves

\[
\frac{1}{T} \sum_{t=1}^{T} \mathbb{E} \left[ \left\| \nabla f(x_t) \right\|^2 \right] \leq \frac{1}{\sqrt{T}} \left[ \frac{G^3}{g_0} (f(x_1) - f(x_*)) + \frac{G^3 d}{(1 - \beta_1)} \| \varepsilon_0^{-1/2} \|_1 + \frac{4L\alpha(1 - \beta_1)}{1 - \beta_1(1 - \gamma)} \right].
\]

Compared with (Chen et al., 2019a, Corollary 3.1), the initial value of \( v_0 = \varepsilon \) only affects one of the terms in our bound, whereas \( \frac{1}{\sqrt{T}} \) appears in all the terms of (Chen et al., 2019a, Corollary 3.1). The reason is that (Chen et al., 2019a) uses \( v_0 \geq \varepsilon \) in many places of the proof, even when it was unnecessary.

Compared with (Zhou et al., 2018, Corollary 3.9), our result allows for bigger values of \( \beta_1 \), since we require \( \beta_2^2 \leq \beta_1 < 1 \) whereas (Zhou et al., 2018, Corollary 3.9) requires \( \beta_1 \leq \beta_2 < 1 \). Moreover, (Zhou et al., 2018, Corollary 3.9) has a constant step size \( \alpha = \frac{1}{\sqrt{T}} \) that requires setting a horizon and becomes very small with large \( d \).

Lastly, we have a log \( T \) dependence, whereas (Zhou et al., 2018, Corollary 3.9) does not. However, this is not for free and it stems from the choice of a constant step size \( \alpha_t = \frac{1}{\sqrt{T}} \) therein. In fact, it is well known that for online gradient descent analysis, log \( T \) can be shaved when \( \alpha_t \approx \frac{1}{\sqrt{T}} \). However, in practice using a variable step size is more favorable, since it does not require setting \( T \) in advance. Therefore, we choose to work with variable step size and have the log \( T \) term in the bound.

### 4.3. Flexible \( \beta_1 \) schedules

We have focused on the case of constant \( \beta_1 \) throughout our paper, as it is the most popular choice in practice. However, it is possible that in some applications, practitioners might see benefit of using other schedules. For instance, one can decrease \( \beta_1 \) until some threshold and keep it constant afterwards. This is not covered by the previous regret analyses as \( \beta_1 \) needed to decrease to 0. With our framework however, one can use not only constant \( \beta_1 \), but any schedule as long as it is nonincreasing, and optimal regret bounds will follow.

Due to space constraints, we do not repeat all the proofs with this modification, but illustrate the main change that happens with variable \( \beta_1 \) and show that our proofs will go through. In this section we switch to notation of \( \beta_{1t} \) to illustrate time-varying case.

We start from the result of Lemma 1, after summing over \( t = 1, \ldots, T \)

\[
\sum_{t=1}^{T} \langle g_t, x_t - x \rangle = \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x \rangle \\
+ \sum_{t=1}^{T} \frac{1}{1 - \beta_{1t}} \langle (m_t, x_t - x) - \langle m_{t-1}, x_{t-1} - x \rangle \rangle \\
- \sum_{t=1}^{T} \beta_{1t} \langle m_{t-1}, x_t - x_{t-1} \rangle. \quad (14)
\]

For bounding the terms on the first and third lines of (14), the only place that will change with varying \( \beta_{1t} \) in the proof, is that \( \alpha_t \| m_t \|_{\nu_{t-1/2}} \) will have a slightly different estimation, since now \( m_t = \sum_{j=1}^{t} \beta_{1(t-k+1)}(1 - \beta_{1j})g_j^2 \). One can use that \( \beta_{1t} \leq \beta_1 \) to obtain the same bounds, but with \( \frac{1}{(1 - \beta_{1t})^2} \) factor multiplying the bounds now. As explained before, this is one thing we lose with varying \( \beta_{1t} \) in theory.

Next, we estimate the terms in the second line of (14)

\[
\frac{1}{1 - \beta_{1t}} \langle (m_t, x_t - x) - \langle m_{t-1}, x_{t-1} - x \rangle \rangle = \\
\frac{1}{1 - \beta_{1t}} \langle m_t, x_t - x \rangle - \frac{1}{1 - \beta_{1(t-1)}} \langle m_{t-1}, x_{t-1} - x \rangle \\
+ \left( \frac{1}{1 - \beta_{1(t-1)}} - \frac{1}{1 - \beta_{1t}} \right) \langle m_{t-1}, x_{t-1} - x \rangle.
\]

Now, for the last line we use that \( \beta_{1t} \) is non-increasing, \( \beta_{1t} \leq \beta_1 \), \( \| m_t \|_1 \leq dG \) and \( \| x_t - x \|_{\infty} \leq D \), to get

\[
\left( \frac{1}{1 - \beta_{1(t-1)}} - \frac{1}{1 - \beta_{1(t-1)}} \right) \langle m_{t-1}, x_{t-1} - x \rangle \\
\leq \frac{dG}{(1 - \beta_1)^2} (\beta_{1(t-1)} - \beta_{1t}). \quad (15)
\]

Thus upon summation over \( t = 1 \) to \( T \), as \( m_0 = 0 \),

\[
\sum_{t=1}^{T} \frac{1}{1 - \beta_{1t}} \langle (m_t, x_t - x) - \langle m_{t-1}, x_{t-1} - x \rangle \rangle \leq \\
\frac{1}{1 - \beta_1 T} \langle m_T, x_T - x \rangle + \frac{dG}{(1 - \beta_1)^2} (\beta_{10} - \beta_{1T}). \quad (16)
\]

where we let \( \beta_{10} = \beta_{11} < 1 \). Indeed, the contribution of this term will only be constant as \( (1 - \beta_{1t}) \leq 1, \forall t \), \( \| m_t \|_{\infty} \leq G, \| x_t - x \|_{\infty} \leq D \).

Note that the estimation of the terms on the first and third lines of (14) are the same, as in the constant \( \beta_1 \) case (up to constants). Also, the contribution of the terms in the second line of (14) with varying \( \beta_{1t} \) is a constant. Thus, one can repeat our proofs, with any nonincreasing \( \beta_{1t} \) schedule and obtain the same optimal regret bounds, but with worse constants (compared to constant \( \beta_1 \) case).
### Acknowledgements

This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement no 725594 - time-data), the Swiss National Science Foundation (SNSF) under grant number 200021_178865/1, the Department of the Navy, Office of Naval Research (ONR) under a grant number N62909-17-1-211, the Hasler Foundation Program: Cyber Human Systems (project number 16066). ### References

A new regret analysis for Adam-type algorithms

A. Proofs

Proof of Lemma 1. By definition of $m_t, g_t = \frac{1}{1-\beta_1}m_t - \frac{\beta_1}{1-\beta_1}m_{t-1}$. Thus, we have

$$\langle g_t, x_t - x \rangle = \frac{1}{1-\beta_1} \langle m_t, x_t - x \rangle - \frac{\beta_1}{1-\beta_1} \langle m_{t-1}, x_t - x \rangle$$

$$= \frac{1}{1-\beta_1} \langle m_t, x_t - x \rangle - \frac{\beta_1}{1-\beta_1} \langle m_{t-1}, x_{t-1} - x \rangle - \frac{\beta_1}{1-\beta_1} \langle m_{t-1}, x_t - x_{t-1} \rangle$$

$$= \frac{1}{1-\beta_1} \langle m_t, x_t - x \rangle - \langle m_{t-1}, x_{t-1} - x \rangle + \langle m_{t-1}, x_t - x_{t-1} \rangle - \frac{\beta_1}{1-\beta_1} \langle m_{t-1}, x_t - x_{t-1} \rangle.$$ 

\[\square\]

A.1. Proofs for AMSGRAD

First, we need a useful inequality.

Lemma 2 (Generalized Hölder inequality, Beckenbach & Bellman, 1961, Chap. 1.18). For $x, y, z \in \mathbb{R}^n_+$ and positive $p, q, r$ such that $\frac{1}{p} + \frac{1}{q} + \frac{1}{r} = 1$, we have

$$\sum_{j=1}^{n} x_j y_j z_j \leq \|x\|_p \|y\|_q \|z\|_r.$$ 

The above lemma is used to obtain a slightly tighter bound for $\|m_t\|_{\tilde{e}_{1/2}^t}$, compared to the standard analysis.

Lemma 3 (Bound for $\|m_t\|_{\tilde{e}_{1/2}^t}$). Under Assumption 1, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \frac{b^2}{m^2} < 1$, $\varepsilon > 0$, and the definitions of $\alpha_t, m_t, v_t, \hat{v}_t$ in AMSGRAD, it holds that

$$\|m_t\|_{\tilde{e}_{1/2}^t}^2 \leq \frac{(1-\beta_1)^2}{\sqrt{(1-\beta_2)(1-\gamma)}} \sum_{i=1}^{t} \sum_{j=1}^{d} \beta_1^t \beta_2^j \beta_{1,j}^t |g_{j,i}|.$$ 

Proof. From the definition of $m_t$ and $v_t$, it follows that

$$m_t = (1-\beta_1) \sum_{j=1}^{t} \beta_1^t \beta_2^j g_j, \quad v_t = (1-\beta_2) \sum_{j=1}^{t} \beta_1^t \beta_2^j g_j^2.$$ 

Then we have

$$\|m_t\|_{\tilde{e}_{1/2}^t}^2 \leq \|m_t\|_{\tilde{e}_{1/2}^t}^2 = \sum_{i=1}^{d} \sum_{j=1}^{d} \beta_1^t \beta_2^j g_{j,i}^2 \leq \frac{(1-\beta_1)^2}{\sqrt{(1-\beta_2)}} \sum_{i=1}^{t} \sum_{j=1}^{d} \beta_1^t \beta_2^j g_{j,i}^2 \leq \frac{(1-\beta_1)^2}{\sqrt{(1-\beta_2)}} \sum_{i=1}^{t} \left( \sum_{j=1}^{d} \beta_1^t \beta_2^j |g_{j,i}| \right)^2 \leq \frac{(1-\beta_1)^2}{\sqrt{(1-\beta_2)}} \sum_{i=1}^{t} \left( \sum_{j=1}^{d} \beta_1^t \beta_2^j \right)^{1/2} \left( \sum_{j=1}^{d} \beta_1^t \beta_2^{j-2} \right)^{1/2} \left( \sum_{j=1}^{d} \beta_1^t \beta_2^{j-2} \right)^{1/2} \leq \frac{(1-\beta_1)^2}{\sqrt{(1-\beta_2)(1-\gamma)}} \sum_{i=1}^{t} \sum_{j=1}^{d} \beta_1^t \beta_2^j |g_{j,i}|.$$ 

where the first inequality follows from the fact that $\hat{v}_{t,i}^{1/2} \geq v_{t,i}^{1/2}$, the second one follows from the generalized Hölder inequality (Lemma 2) for

$$x_j = \beta_2^{t-1} |g_{j,t}|^2, \quad y_j = (\beta_1 \beta_2^{t-2})^{\frac{t-1}{2}}, \quad z_j = (\beta_1^{t-1} |g_{j,t}|) \frac{1}{2} \quad \text{and} \quad p = q = 4, \quad r = 2,$$

and the third one follows from the sum of geometric series and the assumption $\gamma = \frac{\beta_1^2}{\beta_2} < 1$.

We now comment on the possibility of observing many zero gradients in the beginning, causing $v_t = 0$ until some $t$, which would cause the appearance of the indeterminate form $0 \cdot 0$ in the upper bound derived above – specifically in the term $\frac{m_{t,i}^2}{v_{t,i}}$.

For this, we will use the convention $\frac{0}{0} = 0$, in which case the above derivations are always well-defined. For this, we argue as follows: recall first that $v_{t,i} = 0$ if $g_{j,i} = 0$ for all $j = 1, \ldots, t$. This being the case, we also get $m_{t,i} = 0$, and hence, $\frac{m_{t,i}^2}{v_{t,i}} = 0$. In fact, this was done only for convenience, since $\hat{v}_{t,i} \geq \varepsilon$ and we can always exclude zero terms from $\|m_t\|_{\hat{v}_{t-1/2}}^2$, before using the first line in the above chain of inequalities.

**Lemma 4 (Bound for $\sum_{t=1}^{T} \alpha_t \|m_t\|_{\hat{v}_{t-1/2}}^2$).** Under Assumption 1, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \frac{\beta_1^2}{\beta_2} < 1$, $\varepsilon > 0$, and the definitions of $\alpha_t$, $m_t$, $v_t$, $\hat{v}_t$ in AMSGRAD, we have

$$\sum_{t=1}^{T} \alpha_t \|m_t\|_{\hat{v}_{t-1/2}}^2 \leq \frac{(1 - \beta_1)^2}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{t=1}^{T} \alpha_t \sum_{j=1}^{d} \sum_{i=1}^{T} \beta_1^{t-1} |g_{j,i}|$$

(Equation (17))

$$= \frac{(1 - \beta_1)^2}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{t=1}^{T} \sum_{j=1}^{d} \sum_{i=1}^{T} \alpha_t \beta_1^{t-1} |g_{j,i}|$$

(Changing order of summation)

$$\leq \frac{(1 - \beta_1)}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{j=1}^{d} \sum_{i=1}^{T} \alpha_t |g_{j,i}|$$

(Using $\sum_{t=1}^{T} \alpha_t \beta_1^{t-1} \leq \frac{\alpha_j}{1 - \beta_1}$)

$$\leq \frac{1 - \beta_1}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{j=1}^{d} \left( \sum_{i=1}^{T} \alpha_t \right) \left( \sum_{j=1}^{T} g_{j,i}^2 \right)$$

(Cauchy-Schwarz)

$$\leq \frac{(1 - \beta_1)^2}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{i=1}^{d} \left( \sum_{j=1}^{T} g_{j,i}^2 \right)$$

(Using $\sum_{j=1}^{T} \frac{1}{j} \leq 1 + \log T$).

We now restate Theorem 1 for easy navigation and proceed to its proof.

**Theorem 1.** Under Assumption 1, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \frac{\beta_1^2}{\beta_2} < 1$, and $\varepsilon > 0$, AMSGRAD achieves the regret

$$R(T) \leq \frac{D^2 \sqrt{T}}{2(1 - \beta_1)} \sum_{i=1}^{d} v_{T,i}^{1/2} + \frac{\alpha \sqrt{1 + \log T}}{\sqrt{(1 - \beta_2)(1 - \gamma)}} \sum_{i=1}^{d} \left( \sum_{j=1}^{T} g_{j,i}^2 \right).$$

**Proof.** Let $x \in \text{argmin}_{y \in \mathcal{X}} \sum_{t=1}^{T} f_t(y)$. Then by convexity, we immediately have

$$R(T) \leq \sum_{i=1}^{T} \langle g_t, x_t - x \rangle.$$
Hence, our goal is to bound the latter expression. If we sum the inequality from Lemma 1 over \( t = 1, \ldots, T \) and use the fact that \( m_0 = 0 \), we obtain

\[
\sum_{t=1}^{T} \langle g_t, x_t - x \rangle = \frac{1}{1 - \beta_1} \left( \langle m_T, x_T - x \rangle - \langle m_0, x_0 - x \rangle \right) + \langle m_0, x_0 - x \rangle + \sum_{t=1}^{T-1} \langle m_t, x_t - x \rangle \\
+ \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle \\
= \frac{\beta_1}{1 - \beta_1} \langle m_T, x_T - x \rangle + \sum_{t=1}^{T} \langle m_t, x_t - x \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle. \tag{20}
\]

We will separately bound each term in the right-hand side of (20) and then combine these bounds together.

- **Bound for** \( \sum_{t=1}^{T} \langle m_t, x_t - x \rangle \).

As \( x \in \mathcal{X} \), by the nonexpansiveness property (3), we get

\[
\| x_{t+1} - x \|_{\psi_t}^2 = \| P_{\mathcal{A}^t} \left( x_t - \alpha_t \hat{v}_t^{-1/2} m_t \right) - x \|_{\psi_t}^2 \\
\leq \| x_t - \alpha_t \hat{v}_t^{-1/2} m_t - x \|_{\psi_t}^2 \\
= \| x_t - \|_{\psi_t}^2 - 2 \alpha_t \langle m_t, x_t - x \rangle + \| \alpha_t \hat{v}_t^{-1/2} m_t \|_{\psi_t}^2 \\
= \| x_t - \|_{\psi_t}^2 - 2 \alpha_t \langle m_t, x_t - x \rangle + \alpha_t \| m_t \|_{\psi_t}^2. \tag{21}
\]

We rearrange and divide both sides of (21) by \( 2\alpha_t \) to get

\[
\langle m_t, x_t - x \rangle \leq \frac{1}{2\alpha_t} \| x_t - x \|_{\psi_t}^2 - \frac{1}{2\alpha_t} \| x_{t+1} - x \|_{\psi_t}^2 + \frac{\alpha_t}{2} \| m_t \|_{\psi_t}^2 \\
= \frac{1}{2\alpha_{t-1}} \| x_t - x \|_{\psi_t}^2 - \frac{1}{2\alpha_t} \| x_{t+1} - x \|_{\psi_t}^2 + \frac{1}{2} \sum_{i=1}^{d} \left( \frac{\hat{v}_{t,i}^{1/2}}{\alpha_t} - \frac{\hat{v}_{t-1,i}^{1/2}}{\alpha_{t-1}} \right) (x_{t,i} - x_i)^2 + \frac{\alpha_t}{2} \| m_t \|_{\psi_t}^2 \\
\leq \frac{1}{2\alpha_{t-1}} \| x_t - x \|_{\psi_t}^2 - \frac{1}{2\alpha_t} \| x_{t+1} - x \|_{\psi_t}^2 + \frac{D^2}{2} \sum_{i=1}^{d} \left( \frac{\hat{v}_{t,i}^{1/2}}{\alpha_t} - \frac{\hat{v}_{t-1,i}^{1/2}}{\alpha_{t-1}} \right) + \frac{\alpha_t}{2} \| m_t \|_{\psi_t}^2, \tag{22}
\]

where the last inequality is due to the fact that \( \hat{v}_{t,i} \geq \hat{v}_{t-1,i}, \frac{1}{\alpha_t} \geq \frac{1}{\alpha_{t-1}} \), and the definition of \( D \).\(^1\)

Summing (22) over \( t = 1, \ldots, T \) and using that \( \frac{1}{2\alpha_0} \| x_1 - x \|_{\psi_0}^2 = 0 \) yields

\[
\sum_{t=1}^{T} \langle m_t, x_t - x \rangle \leq \frac{D^2}{2\alpha_T} \sum_{i=1}^{d} \hat{v}_{T,i}^{1/2} + \frac{1}{2} \sum_{t=1}^{T} \alpha_t \| m_t \|_{\psi_t}^2. \tag{23}
\]

- **Bound for** \( \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle \).

Now let us bound the last term in (20).

\[
\sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle = \sum_{t=2}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle = \sum_{t=1}^{T-1} \langle m_t, x_t - x_{t+1} \rangle \\
\leq \sum_{t=1}^{T-1} \| m_t \|_{\psi_t}^2 \| x_{t+1} - x_t \|_{\psi_t}. \tag{Hölder inequality}
\]

\(^1\)Note that for \( t = 1 \) we suppose that \( \frac{1}{\alpha_0} = 0 \); this makes the above derivation still valid, as \( \alpha_0 \) is not used in the algorithm, and this is only for convenience.
We first give analogous results to Lemmas 3 and 4, which are mostly standard and simplified thanks to a constant $\beta$.

We now have all the ingredients required to bound the right-hand side of (20). To that end, after all substitutions and some straightforward algebra, we obtain

$$\sum_{t=1}^{T-1} \|m_t\| \frac{\beta_1}{(1 - \beta_1)} \left(\langle m_T, x_T - x \rangle + \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle + \sum_{t=1}^{T} \langle m_t, x_t - x \rangle \right)$$

$$\leq \frac{\beta_1}{1 - \beta_1} \left( \frac{D^2}{2\alpha T} \sum_{i=1}^{d} \frac{1 + \beta_1}{2(1 - \beta_1)} \sum_{t=1}^{T} \alpha_t \|m_t\|^2 \frac{1}{v_t} \right)$$

$$\leq \frac{D^2 \sqrt{T}}{2\alpha (1 - \beta_1)} \sum_{i=1}^{d} \frac{1}{v_T^{1/2}} + \frac{\alpha \sqrt{1 + \log T}}{(1 - \beta_2)(1 - \gamma)} \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i}^{2/3}$$

where the second inequality follows from the assumption $\frac{2 - \beta_1}{4} \leq \frac{1}{2}, \frac{1 + \beta_1}{2} \leq 1$, and $\alpha_T = \frac{\alpha}{\sqrt{T}}$, and the last follows by Lemma 4.

\[\Box\]

**A.2. Proofs for ADAMNC**

We first give analogous results to Lemmas 3 and 4, which are mostly standard and simplified thanks to a constant $\beta_1$.

**Lemma 5** (Bound for $\|m_t\|^2_{v_t^{-1/2}}$). Under Assumption 1, $\beta_1 < 1, \varepsilon > 0$, and the definitions of $\alpha_t, m_t, v_t$ in ADAMNC, it holds that

$$\|m_t\|^2_{v_t^{-1/2}} \leq \sqrt{t} (1 - \beta_1) \sum_{i=1}^{d} \sum_{j=1}^{t} \frac{\beta_1^{t-j} g_{t,i}^2}{\sqrt{\sum_{k=1}^{j} g_{k,i}^2}}.$$
Proof. Using the expression (18) for $m_t$ and $\alpha_{t,i} = \frac{1}{t} \left( \sum_{j=1}^{t} \frac{g_{j,i}^2}{\beta_1} + \varepsilon \right)$, we obtain:\(^2\)

\[
\|m_t\|_{\nu_{t,1/2}}^2 = \sum_{i=1}^{d} \frac{m_{t,i}^2}{\nu_{t,1/2}} = \sum_{i=1}^{d} \frac{\left( \sum_{j=1}^{t} (1 - \beta_1) \beta_1^{t-j} g_{j,i} \right)^2}{\sqrt{\frac{1}{t} \left( \varepsilon + \sum_{k=1}^{t} g_{k,i}^2 \right)}}
\]

\[
\leq \sqrt{t}(1 - \beta_1)^2 \sum_{i=1}^{d} \frac{\left( \sum_{j=1}^{t} (1 - \beta_1) \beta_1^{t-j} g_{j,i} \right)^2}{\sqrt{\sum_{k=1}^{t} g_{k,i}^2}}
\]

\[
\leq \sqrt{t}(1 - \beta_1)^2 \sum_{i=1}^{d} \frac{\left( \sum_{j=1}^{t} (1 - \beta_1) \beta_1^{t-j} g_{j,i}^2 \right) \left( \sum_{j=1}^{t} (1 - \beta_1) \beta_1^{t-j} \right)}{\sqrt{\sum_{k=1}^{t} g_{k,i}^2}^{2}}
\]

where the first inequality is due to $\varepsilon > 0$, second inequality is by Cauchy-Schwarz, the third one by the sum of geometric series, and the final one is by $j \leq t$. \hfill \Box

Lemma 6 (Bound for $\sum_{t=1}^{T} \alpha_t\|m_t\|_{\nu_{t,1/2}}^2$). Under Assumption 1, $\beta_1 < 1$, $\varepsilon > 0$, and the definitions of $\alpha_t$, $m_t$, $\nu_t$ in ADAMNC, it holds that

\[
\sum_{t=1}^{T} \alpha_t\|m_t\|_{\nu_{t,1/2}}^2 \leq 2\alpha \sum_{i=1}^{d} \left( \sum_{t=1}^{T} g_{t,i}^2 \right).
\]

Proof. We have, by using Lemma 5

\[
\sum_{t=1}^{T} \alpha_t\|m_t\|_{\nu_{t,1/2}}^2 = \sum_{t=1}^{T} \alpha_t \sqrt{t}(1 - \beta_1)^2 \sum_{i=1}^{d} \frac{\left( \sum_{j=1}^{t} (1 - \beta_1) \beta_1^{t-j} g_{j,i} \right)^2}{\sqrt{\sum_{k=1}^{t} g_{k,i}^2}}
\]

\[
= \alpha (1 - \beta_1)^2 \sum_{i=1}^{d} \sum_{t=1}^{T} \frac{\beta_1^{t-j} g_{j,i}^2}{\sqrt{\sum_{k=1}^{t} g_{k,i}^2}}
\]

\[
= \alpha (1 - \beta_1)^2 \sum_{i=1}^{d} \sum_{t=1}^{T} \frac{\beta_1^{t-j} g_{j,i}^2}{\sqrt{\sum_{k=1}^{t} g_{k,i}^2}}
\]

where the second equality is due to $\alpha_t = \frac{\alpha}{t}$, third equality is by changing the order of summation, first inequality by summation of the geometric series. For the last inequality, we use a standard inequality for numerical sequences, encountered for example in Auer et al. (2002, Lemma 3.5)

\[
\sum_{j=1}^{T} \frac{a_j}{\sqrt{\sum_{k=1}^{j} a_k}} \leq 2 \sqrt{\sum_{j=1}^{T} a_j} \quad \text{for all } a_1, \ldots, a_T \geq 0.
\]
We now restate Theorem 2 and present its proof.

**Theorem 2.** Under Assumption 1, \( \beta_1 < 1 \), and \( \varepsilon > 0 \), ADAMNC enjoys the regret bound

\[
R(T) \leq \frac{D^2 \sqrt{T}}{2\alpha (1 - \beta_1)} \sum_{t=1}^{d} v_{1/2}^t + \frac{2\alpha}{1 - \beta_1} \sum_{t=1}^{d} \sqrt{T} \left( \sum_{i=1}^{g_{t,i}} \right).
\]

**Proof.** We will follow the proof structure of Theorem 1. First, we start from (20) which applies to ADAMNC as the update of \( m_t \) is the same as AMSGRAD

\[
R(T) \leq \sum_{t=1}^{T} \langle g_t, x_t - x \rangle = \frac{\beta_1}{1 - \beta_1} \langle m_T, x_T - x \rangle + \sum_{t=1}^{T} \langle m_t, x_t - x \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle.
\] (29)

Then we again bound each term in the right-hand side separately.

- **Bound for** \( \sum_{t=1}^{T} \langle m_t, x_t - x \rangle \).

We proceed similarly to the derivations in (21) and (22), the main change being that we now have \( v_t \) instead of \( \hat{v}_t \). We have:

\[
\langle m_t, x_t - x \rangle \leq \frac{1}{2\alpha t} \| x_t - x \|^2_{v_{t/2}} - \frac{1}{2\alpha} \| x_{t+1} - x \|^2_{v_{t/2}} + \frac{1}{2} \sum_{t=1}^{d} \left( \frac{v_{t+1/2,i}}{\alpha_t} - \frac{v_{t-1/2,i}}{\alpha_{t-1}} \right) (x_{t,i} - x_i)^2 + \frac{\alpha_t}{2} \| m_t \|^2_{v_{t/2}}.
\]

where the last inequality is due to \( \frac{v_{t+1/2,i}}{\alpha_t} \geq \frac{v_{t-1/2,i}}{\alpha_{t-1}} \), since by definition \( v_{t,i} = \frac{1}{t} \sum_{j=1}^{t} g_{j,i} \) and \( \alpha_t = \frac{\alpha}{\sqrt{t}} \).

We now proceed to telescope this inequality, assuming as before that \( \frac{1}{\alpha} = 0 \). Doing so, we obtain:

\[
\sum_{t=1}^{T} \langle m_t, x_t - x \rangle \leq \frac{D^2}{2} \sum_{t=1}^{d} \frac{v_{t/2}}{\alpha_T} + \sum_{t=1}^{T} \alpha_t \| m_t \|^2_{v_{t/2}}.
\] (31)

- **Bounds for** \( \langle m_T, x_T - x \rangle \) and \( \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle \)

These bounds will be similar as in the proof of Theorem 1. Again, the only change in calculations in (24) and (25) is that now we have \( v_t \) instead of \( \hat{v}_t \)

\[
\sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle \leq \sum_{t=1}^{T-1} \alpha_t \| m_t \|^2_{v_{t-1/2}},
\] (32)

and

\[
\langle m_T, x_T - x \rangle \leq \alpha_T \| m_T \|^2_{v_{1/2}} + \frac{D^2}{4\alpha_T} \sum_{t=1}^{d} v_{1/2,i}.
\] (33)

We now combine (31), (32), and (33) in (29), estimate using the same steps in (26), and use the bound for \( \sum_{t=1}^{T} \alpha_t \| m_t \|^2_{v_{1/2}} \) from Lemma 6 to conclude:

\[
\sum_{t=1}^{T} \langle g_t, x_t - x \rangle = \frac{\beta_1}{1 - \beta_1} \langle m_T, x_T - x \rangle + \sum_{t=1}^{T} \langle m_t, x_t - x \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle
\]

\[
\leq \left( \frac{D^2}{2} + \frac{\beta_1 D^2}{4(1 - \beta_1)} \right) \sum_{i=1}^{d} v_{1/2,i} + \left( \frac{1}{2} + \frac{\beta_1}{1 - \beta_1} \right) \sum_{t=1}^{T} \alpha_t \| m_t \|^2_{v_{t-1/2}}
\]

\[
\leq \frac{D^2 \sqrt{T}}{2\alpha(1 - \beta_1)} \sum_{i=1}^{d} v_{1/2,i} + \frac{2\alpha}{1 - \beta_1} \sum_{t=1}^{T} \sqrt{\sum_{i=1}^{g_{t,i}}}
\]
A.3. Proofs for SADAM

Lemma 7 (Bound for \(\|m_t\|_{v_{t-1}}^2\)). Under Assumption 1, \(\beta_1 < 1, \varepsilon > 0\), and the definitions of \(\alpha_t, m_t, v_t, \hat{v}_t\) in SADAM, it holds that

\[
\|m_t\|_{v_{t-1}}^2 \leq t(1 - \beta_1) \sum_{i=1}^d \sum_{j=1}^t \frac{\beta_1^{t-j} g_{j,i}^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon}.
\]  

(34)

Proof. We have

\[
\|m_t\|_{v_{t-1}}^2 = \sum_{i=1}^d m_{t,i}^2 = \sum_{i=1}^d \langle v_{t,i}, \hat{v}_{t,i} \rangle = t(1 - \beta_1)^2 \sum_{i=1}^d \frac{\left(\sum_{j=1}^t \beta_1^{t-j} g_{j,i}^2\right)^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon},
\]

where we used the definitions \(\hat{v}_{t,i} = \frac{1}{t} \sum_{k=1}^t g_{k,i}^2 + \frac{\varepsilon}{t}\) and the expression for \(m_t\) from (18) in the first line. First inequality follows from Cauchy-Schwarz and sum of geometric series; and the last inequality is by \(j \leq t\).

Lemma 8 (Bound for \(\sum_{t=1}^T \alpha_t \|m_t\|_{v_{t-1}}^2\)). Under Assumption 1, \(\beta_1 < 1, \varepsilon > 0\), and the definitions of \(\alpha_t, m_t, v_t, \hat{v}_t\) in SADAM, it holds that

\[
\sum_{t=1}^T \alpha_t \|m_t\|_{v_{t-1}}^2 \leq \alpha \sum_{i=1}^d \log \left(\frac{\sum_{t=1}^T g_{t,i}^2}{\varepsilon} + 1\right).
\]  

(36)

Proof. We have, by Lemma 7

\[
\sum_{t=1}^T \alpha_t \|m_t\|_{v_{t-1}}^2 = \sum_{t=1}^T \alpha_t t(1 - \beta) \sum_{i=1}^d \sum_{j=1}^t \frac{\beta_1^{t-j} g_{j,i}^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon}
\]

\[
= \alpha (1 - \beta) \sum_{i=1}^d \sum_{t=1}^T \sum_{j=1}^t \frac{\beta_1^{t-j} g_{j,i}^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon}
\]

\[
= \alpha (1 - \beta) \sum_{i=1}^d \sum_{t=1}^T \sum_{j=1}^t \frac{\beta_1^{t-j} g_{j,i}^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon}
\]

\[
\leq \alpha \sum_{i=1}^d \sum_{t=1}^T \frac{g_{t,i}^2}{\sum_{k=1}^d g_{k,i}^2 + \varepsilon} \leq \alpha \sum_{i=1}^d \log \left(\frac{\sum_{t=1}^T g_{t,i}^2}{\varepsilon} + 1\right),
\]  

(37)

where the second equality is by the definition of \(\alpha_i\) and the third equality is by changing the order of summation. Moreover, first inequality is by the sum of geometric series and the last inequality is due to the fact that

\[
\sum_{j=1}^T \frac{a_j}{\sum_{k=1}^d a_k + \varepsilon} \leq \log \left(\frac{\sum_{j=1}^T a_j}{\varepsilon} + 1\right),
\]

(38)

for nonnegative \(a_1, \ldots, a_T\) and \(\varepsilon > 0\) – see e.g., Duchi et al. (2010, Lemma 12) and Hazan et al. (2007, Lemma 11).

We now restate Theorem 3 and present its proof.

Theorem 3. Let Assumption 1 hold and \(f_t\) be \(\mu\)-strongly convex, \(\forall t\). Then, if \(\beta_1 < 1, \varepsilon > 0\), and \(\alpha \geq \frac{\phi^2}{\mu}\) SADAM achieves

\[
R(T) \leq \frac{\beta_1 dGD}{1 - \beta_1} + \frac{\alpha}{1 - \beta_1} \sum_{i=1}^d \log \left(\frac{\sum_{t=1}^T g_{k,i}^2}{\varepsilon} + 1\right).
\]
We finalize by using $1 + \frac{\alpha}{2}$. We sum the above inequality and use the fact that $\hat{\beta}$.

We want to estimate $\sum_{t=1}^{T} \langle g_t, x_t - x \rangle$. Similarly to (20), we have

$$\sum_{t=1}^{T} \langle g_t, x_t - x \rangle \leq \frac{\beta_1}{1 - \beta_1} \langle m_{T}, x_T - x \rangle + \sum_{t=1}^{T} \langle m_{t}, x_t - x \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle.$$  

**Bound for $\sum_{t=1}^{T} \langle m_t, x_t - x \rangle$**

We proceed similarly to (21) and (22). The only change is that now we have $\tilde{v}_t$ instead of $\tilde{v}_t^{1/2}$

$$\langle m_{t}, x_t - x \rangle \leq \frac{1}{2\alpha - 1} \| x_t - x \|_2^2 - \frac{1}{2\alpha} \| x_{t+1} - x \|_2^2 \tilde{v}_t + \frac{1}{2} \sum_{t=1}^{d} (\tilde{v}_{t,i} - \frac{\tilde{v}_{t-1,i}}{\alpha}) (x_{t,i} - x_{i-1})^2 + \frac{\alpha}{2} \| m_t \|_2^2 \tilde{v}_t.$$  

We sum the above inequality and use the fact that $\frac{1}{2\alpha} \| x_t - x \|_2^2 \tilde{v}_t = 0$ to obtain

$$\sum_{t=1}^{T} \langle m_{t}, x_t - x \rangle \leq \sum_{t=1}^{T} \sum_{t=1}^{d} \left( \frac{\tilde{v}_{t,i} - \frac{\tilde{v}_{t-1,i}}{\alpha}}{2\alpha} \right) (x_{t,i} - x_{i-1})^2 + \sum_{t=1}^{T} \frac{\alpha}{2} \| m_t \|_2^2 \tilde{v}_t.$$  

**Bound for $\sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle$**

This bound will be similar to the one we derived for Theorem 1. The main change in the calculations of (24) is that we will have $\tilde{v}_t$ instead of $\tilde{v}_t^{1/2}$ for using Hölder’s inequality and nonexpansiveness

$$\sum_{t=1}^{T} \langle m_{t-1}, x_{t-1} - x_t \rangle \leq \sum_{t=1}^{T-1} \alpha_t \| m_t \|_{\tilde{v}_t}^2 \leq \sum_{t=1}^{T} \alpha_t \| m_t \|_{\tilde{v}_t}^2.$$  

We collect these estimations in (40) and (39) to derive

$$R(T) = \sum_{t=1}^{T} f_t(x_t) - f_t(x) \leq \frac{\beta_1}{1 - \beta_1} \langle m_{T}, x_T - x \rangle + \frac{1 + \beta_1}{2(1 - \beta_1)} \sum_{t=1}^{T} \alpha_t \| m_t \|_{\tilde{v}_t}^2,$$

$$+ \sum_{t=1}^{T} \sum_{i=1}^{d} \left( \frac{\tilde{v}_{t,i} - \frac{\tilde{v}_{t-1,i}}{\alpha}}{2\alpha} \right) (x_{t,i} - x_{i-1})^2 - \sum_{t=1}^{T} \sum_{t=1}^{d} \frac{\mu}{2} (x_{t,i} - x_{i-1})^2.$$  

We collect the last two terms and use the assumption on the step size $\alpha \geq \frac{\alpha^2}{\mu}$ and the definition $\hat{v}_{t,i} = \frac{1}{\beta} \sum_{j=1}^{t} g_{j,i} + \frac{\xi}{\mu}$ to derive

$$\frac{\hat{v}_{t,i} - \hat{v}_{t-1,i}}{2\alpha} - \frac{\mu}{2} \leq 0.$$  

Thus, (43) becomes

$$\sum_{t=1}^{T} f_t(x_t) - f_t(x) \leq \frac{\beta_1}{1 - \beta_1} \langle m_{T}, x_T - x \rangle + \frac{1 + \beta_1}{2(1 - \beta_1)} \sum_{t=1}^{T} \alpha_t \| m_t \|_{\tilde{v}_t}^2.$$  

We finalize by using $\frac{1 + \beta_1}{2} \leq 1$, Lemma 8 for the last term, and $\| m_t \|_{\infty} \leq G_i \| x_t - x \|_{\infty} \leq D$ for the first term

$$\sum_{t=1}^{T} f_t(x_t) - f_t(x) \leq \frac{\beta_1 d G D}{1 - \beta_1} + \frac{\alpha}{1 - \beta_1} \sum_{i=1}^{d} \log \left( \frac{\sum_{t=1}^{T} g_{t,i}^2}{\varepsilon} + 1 \right).$$
A.4. Proof for Zeroth order ADAM

We restate Proposition 1 and provide its proof.

**Proposition 1.** Assume that $f$ is convex, $L$-smooth, and $L_c$-Lipschitz, $\mathcal{X}$ is compact with diameter $D$. Then ZO-AdaMM with $\beta_1, \beta_2 < 1$, $\gamma = \frac{\beta_1^2}{\beta_2} < 1$ achieves

$$
\mathbb{E} \left[ \sum_{t=1}^{T} f_t(x_t) - f_t(x_*) \right] \leq \frac{D^2 \sqrt{T}}{2\alpha (1 - \beta_1)} \sum_{i=1}^{d} \mathbb{E} \left[ \hat{v}_{T,i}^{1/2} \right] + \frac{\alpha \sqrt{1 + \log T}}{\sqrt{1 - \beta_2}(1 - \gamma)} \sum_{i=1}^{d} \sqrt{\sum_{t=1}^{T} \mathbb{E} \left[ \hat{g}_{t,i}^2 \right]}. 
$$

**Proof.** We first note that ZO-AdaMM (Chen et al., 2019b) corresponds to using AMSGRAD with $\hat{g}_t$ as the gradient input, rather than the true gradient $g_t$. Therefore, we follow the proof structure of Theorem 1 with $\hat{g}_t$ as gradient input (instead of the true gradient $g_t$), until (26):

$$
\sum_{t=1}^{T} \langle \hat{g}_t, x_t - x \rangle \leq \frac{D^2 \sqrt{T}}{2\alpha (1 - \beta_1)} \sum_{i=1}^{d} \mathbb{E} \left[ \hat{v}_{T,i}^{1/2} \right] + \frac{\alpha \sqrt{1 + \log T}}{\sqrt{1 - \beta_2}(1 - \gamma)} \sum_{i=1}^{d} \sqrt{\sum_{t=1}^{T} \mathbb{E} \left[ \hat{g}_{t,i}^2 \right]}. 
$$

With this bound in hand, we proceed as in the proof of Chen et al. (2019b, Proposition 4). Specifically, note that $\mathbb{E}_t [\hat{g}_t] = \nabla f_t(x_t)$ where the randomness is due to selection of the seed $\xi_t$ and the random vector $u$ in (12). Then, taking the full expectation and using convexity gives

$$
\mathbb{E} \left[ \sum_{t=1}^{T} f_t(x_t) - f_t(x) \right] \leq \mathbb{E} \left[ \sum_{t=1}^{T} \langle \hat{g}_t, x_t - x \rangle \right].
$$

Our claim then follows by applying Jensen’s inequality, after taking expectations in (44). \qed

A.5. Proofs for nonconvex AMSGRAD

**Lemma 9.** (Bound for $\sum_{t=1}^{T} \| \alpha_t \hat{v}_t^{-1/2} m_t \|^2$) Under Assumption 2, $\beta_1 < 1$, $\beta_2 < 1$, $\gamma = \frac{\beta_1^2}{\beta_2} < 1$, and the definitions of $\alpha_t$, $m_t$, $v_t$, $\hat{v}_t$ in AMSGRAD, it holds that

$$
\sum_{t=1}^{T} \| \alpha_t \hat{v}_t^{-1/2} m_t \|^2 \leq \frac{d(1 - \beta_1)^2 \alpha^2 (1 + \log T)}{(1 - \beta_2)(1 - \gamma)}. 
$$

**Proof.** We first note the inequality for positive numbers

$$
\frac{(a_1 + \cdots + a_t)^2}{b_1 + \cdots + b_t} \leq \frac{a_1^2}{b_1} + \cdots + \frac{a_t^2}{b_t},
$$

which is a consequence of Cauchy-Schwarz inequality.

Now we have

$$
\| \alpha_t \hat{v}_t^{-1/2} m_t \|^2 = \sum_{i=1}^{d} \alpha_t^2 \frac{m_{t,i}^2}{v_{t,i}} \leq \sum_{i=1}^{d} \alpha_t^2 \frac{m_{t,i}^2}{v_{t,i}} = \sum_{i=1}^{d} \alpha_t^2 \left( \frac{\sum_{j=1}^{t} (1 - \beta_1) \hat{v}_{t-j,i} g_{t-j,i}}{\sum_{j=1}^{t} (1 - \beta_2) \hat{v}_{t-j,i} g_{t-j,i}} \right) ^2
$$

$$
\leq \frac{(1 - \beta_1)^2}{1 - \beta_2} \sum_{i=1}^{d} \alpha_t^2 \sum_{j=1}^{t} \frac{g_{t-j,i}^2}{\beta_2^{t-j} g_{t-j,i}^2} \leq \frac{(1 - \beta_1)^2}{1 - \beta_2} \sum_{i=1}^{d} \alpha_t^2 \sum_{j=1}^{t} \gamma^{t-j}.
$$
A new regret analysis for Adam-type algorithms

\[
\leq \frac{d(1 - \beta_1)^2}{(1 - \beta_2)(1 - \gamma)} \alpha_t^2,
\]

(47)

where the first inequality uses $\hat{v}_{t,i} \geq v_{t,i}$, and the second equality uses the expressions from (18). The second inequality is by (46), and the final one by the sum of geometric series with $\gamma = \frac{\beta_2}{\beta_1}$. Since $\alpha_t^2 = \beta_t^2$, the final inequality (45) follows. \Box

The reader could notice that all proofs so far were based on Lemma 1. In fact, we can formulate a more general statement, which will be the key in the nonconvex settings.

**Lemma 10.** Let $m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t$ and $A_t \in \mathbb{R}^d, \forall t = 1, \ldots, T$. Then it follows that

\[
\langle A_t, g_t \rangle = \frac{1}{1 - \beta_1} \left( \langle A_t, m_t \rangle - \langle A_{t-1}, m_{t-1} \rangle \right) + \frac{\beta_1}{1 - \beta_1} \langle A_{t-1} - A_t, m_{t-1} \rangle.
\]

(48)

For convex case, we plugged in $A_t = x_t - x$, while for the nonconvex case we will use $A_t = \alpha_t \hat{v}_{t}^{-1/2} \nabla f(x_t)$. Obviously, its proof relies on the same algebra as in Lemma 1.

We move onto restating Theorem 4 and presenting its proof.

**Theorem 4.** Under Assumption 2, $\beta_1 < 1$, $\beta_2 < 1$, and $\gamma = \frac{\beta_2}{\beta_1} < 1$ AMSGRAD achieves

\[
\frac{1}{T} \sum_{t=1}^{T} \mathbb{E} \left[ \| \nabla f(x_t) \|^2 \right] \leq \frac{1}{\sqrt{T}} \left[ \frac{G^3 \alpha^2 (f(x_1) - f(x_*)) + \frac{G^3}{(1 - \beta_1)} \| \epsilon_0^{-1/2} \|^2_1}{4Ld(1 - \beta_1)} \right. + \frac{GLd\alpha(1 - \beta_1)(1 + \log T)}{(1 - \beta_2)(1 - \gamma)}.
\]

Proof. Let $A_t = \alpha_t \hat{v}_{t}^{-1/2} \nabla f(x_t)$ for $t \geq 1$ and $A_0 = A_1$. By summing (48) over $t = 1, \ldots, T$ and using that $m_0 = 0$, $\langle A_0, m_0 \rangle = 0$, $\langle A_1 - A_0, m_0 \rangle = 0$, we obtain

\[
\sum_{t=1}^{T} \langle A_t, g_t \rangle = \frac{1}{1 - \beta_1} \langle A_T, m_T \rangle + \sum_{t=1}^{T-1} \langle A_t, m_t \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle A_{t-1} - A_t, m_{t-1} \rangle
\]

\[
= \frac{\beta_1}{1 - \beta_1} \langle A_T, m_T \rangle + \sum_{t=1}^{T} \langle A_t, m_t \rangle + \frac{\beta_1}{1 - \beta_1} \sum_{t=1}^{T} \langle A_t - A_{t+1}, m_t \rangle.
\]

(49)

We are going to derive bounds for (49) and then take expectation to get an estimate for $\mathbb{E} \left[ \| \nabla f(x_t) \|^2 \right]$.

To this end, we note that for the expectation conditioned on the history until selecting $g_t$, one has $\mathbb{E}_t[\langle g_t \rangle] = \nabla f(x_t)$, since under this condition $\hat{v}_{t-1}$ is deterministic as it does not depend on $g_t$. It is tempting to compute $\mathbb{E}_t \left[ \langle A_t, g_t \rangle \right]$ by using $\mathbb{E}_t \left[ \langle A_t, g_t \rangle \right] = \mathbb{E}_t \left[ \langle \alpha_t \hat{v}_{t}^{-1/2} \nabla f(x_t), g_t \rangle \right]$. Unfortunately, this is not feasible, as $\hat{v}_{t}$ does depend on $g_t$. Instead, we bound $\langle A_t, g_t \rangle$ from below by a more suitable random variable for taking conditional expectation $\mathbb{E}_t$.

- **Bound for $\langle A_t, g_t \rangle$**

First, we note

\[
\langle A_t, g_t \rangle = \langle \alpha_t \hat{v}_{t}^{-1/2} \nabla f(x_t), g_t \rangle = \langle \alpha_{t-1} \hat{v}_{t}^{-1/2} \nabla f(x_t), g_t \rangle - \langle \nabla f(x_t), (\alpha_{t-1} \hat{v}_{t}^{-1/2} - \alpha_t \hat{v}_{t}^{-1/2}) g_t \rangle.
\]

(50)

To simplify derivations, we set $\alpha_0 = \alpha = \alpha_1$. Now, for the last term in the right-hand side we have

\[
\langle \nabla f(x_t), (\alpha_{t-1} \hat{v}_{t-1}^{-1/2} - \alpha_t \hat{v}_{t}^{-1/2}) g_t \rangle \leq \| \nabla f(x_t) \|_1 \| \alpha_{t-1} \hat{v}_{t-1}^{-1/2} - \alpha_t \hat{v}_{t}^{-1/2} \|_1 \| g_t \|_1
\]

\[
\leq G^2 \left( \| \alpha_{t-1} \hat{v}_{t-1}^{-1/2} \|_1 - \| \alpha_t \hat{v}_{t}^{-1/2} \|_1 \right),
\]

(51)

where we used Hölder’s inequality, and $\alpha_{t-1} \hat{v}_{t-1}^{-1/2} \geq \alpha \hat{v}_{t, t}^{-1/2}$ (note that for $t = 1$, this is still true, since $\hat{v}_{1} \geq \hat{v}_0$ and $\alpha_0 = \alpha_1$). Combining (51) and (50) yields

\[
\langle A_t, g_t \rangle \geq \langle \alpha_{t-1} \hat{v}_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle - G^2 (\| \alpha_{t-1} \hat{v}_{t-1}^{-1/2} \|_1 - \| \alpha_t \hat{v}_{t}^{-1/2} \|_1).
\]

(52)
Clearly, the term $\langle \alpha_t \hat{v}_t^{-1/2} \nabla f(x_t), g_t \rangle$ is more convenient for taking $E_t$. We will do it right after we bound the right-hand side of (49). Let us focus on each term of (49) separately.

**Bound for $\langle A_t - A_{t+1}, m_t \rangle$**

We rearrange terms to obtain

$$\langle A_t - A_{t+1}, m_t \rangle = \langle \alpha_t \hat{v}_t^{-1/2} \nabla f(x_t) - \alpha_{t+1} \hat{v}_{t+1}^{-1/2} \nabla f(x_{t+1}), m_t \rangle$$

$$= \langle \alpha_t \hat{v}_t^{-1/2} \nabla f(x_{t+1}) - \alpha_{t+1} \hat{v}_{t+1}^{-1/2} \nabla f(x_{t+1}), m_t \rangle + \langle \alpha_t \hat{v}_t^{-1/2} \nabla f(x_t) - \alpha_{t+1} \hat{v}_{t+1}^{-1/2} \nabla f(x_{t+1}), m_t \rangle$$

$$= \langle \nabla f(x_{t+1}), (\alpha_t \hat{v}_t^{-1/2} - \alpha_{t+1} \hat{v}_{t+1}^{-1/2}) m_t \rangle + \langle \nabla f(x_t) - \nabla f(x_{t+1}), \alpha_t \hat{v}_t^{-1/2} m_t \rangle. \tag{53}$$

For the first term we use almost the same inequality as in (51)

$$\langle \nabla f(x_{t+1}), (\alpha_t \hat{v}_t^{-1/2} - \alpha_{t+1} \hat{v}_{t+1}^{-1/2}) m_t \rangle \leq \|\nabla f(x_{t+1})\|_\infty \|\alpha_t \hat{v}_t^{-1/2} - \alpha_{t+1} \hat{v}_{t+1}^{-1/2}\|_1 m_t \|_\infty$$

$$\leq G^2 \left( \|\alpha_t \hat{v}_t^{-1/2}\|_1 - \|\alpha_{t+1} \hat{v}_{t+1}^{-1/2}\|_1 \right).$$

For the second term we use smoothness of $f$ and the update rule for $x_{t+1}$

$$\langle \nabla f(x_t) - \nabla f(x_{t+1}), \alpha_t \hat{v}_t^{-1/2} m_t \rangle \leq \|\nabla f(x_t) - \nabla f(x_{t+1})\| \|\alpha_t \hat{v}_t^{-1/2} m_t\|$$

$$\leq L \|x_{t+1} - x_t\| \|\alpha_t \hat{v}_t^{-1/2} m_t\| = L \|x_{t+1} - x_t\|^2.$$

We apply above estimates in (53) to derive

$$\langle A_t - A_{t+1}, m_t \rangle \leq G^2 \left( \|\alpha_t \hat{v}_t^{-1/2}\|_1 - \|\alpha_{t+1} \hat{v}_{t+1}^{-1/2}\|_1 \right) + L \|x_{t+1} - x_t\|^2. \tag{54}$$

**Bound for $\langle A_t, m_t \rangle$**

By the update of $x_{t+1}$ and the descent lemma, we have

$$\langle A_t, m_t \rangle = \langle \alpha_t \hat{v}_t^{-1/2} \nabla f(x_t), m_t \rangle = \langle \nabla f(x_t), \alpha_t \hat{v}_t^{-1/2} m_t \rangle$$

$$= \langle \nabla f(x_t), x_t - x_{t+1} \rangle \leq f(x_t) - f(x_{T+1}) + \frac{L}{2} \|x_{t+1} - x_t\|^2. \tag{55}$$

**Final bounds**

Combining the bounds, we obtain

RHS of (49) \leq \frac{\beta_1}{1 - \beta_1} \langle A_T, m_T \rangle + (f(x_1) - f(x_{T+1}) + \frac{L}{2} \sum_{t=1}^T \|x_{t+1} - x_t\|^2)

$$+ \frac{\beta_1 G^2}{1 - \beta_1} \left( \|\alpha_1 \hat{v}_1^{-1/2}\|_1 - \|\alpha_T \hat{v}_T^{-1/2}\|_1 \right) + \frac{\beta_1 L}{1 - \beta_1} \sum_{t=1}^{T-1} \|x_{t+1} - x_t\|^2. \tag{56}$$

By Young’s inequality, $x_T - x_{T+1} = \alpha_T \hat{v}_T^{-1/2} m_T$, and $\|\nabla f(x_T)\|_\infty \leq G$, $\langle A_T, m_T \rangle = \langle \nabla f(x_T), \alpha_T \hat{v}_T^{-1/2} m_T \rangle \leq L \|\alpha_T \hat{v}_T^{-1/2} m_T\|^2 + \frac{1}{4L} \|\nabla f(x_T)\|^2 \leq \|x_{T+1} - x_T\|^2 + \frac{G^2 d}{4L}.$

Hence, we can conclude in (56)

RHS of (49) \leq \frac{\beta_1 G^2 d}{4(1 - \beta_1)} + (f(x_1) - f(x_{T+1}) + \frac{L}{2} \sum_{t=1}^T \|x_{t+1} - x_t\|^2) + \frac{\beta_1 G^2}{1 - \beta_1} \|\alpha_1 \hat{v}_1^{-1/2}\|_1

$$+ \frac{\beta_1 L}{1 - \beta_1} \sum_{t=1}^T \|x_{t+1} - x_t\|^2.$$
where we used in the second inequality we used \( f(x_T) \geq f(x_*) \), \( \alpha_1 = \alpha \), and \( \frac{1 + \beta_1}{2} \leq 1 \) and the final inequality follows from Lemma 9, as \( \sum_{t=1}^{T} \|x_{t+1} - x_t\|^2 = \sum_{t=1}^{T} \|\alpha_t \hat v_t^{-1/2} m_t\|^2 \).

Now we analyze the left-hand side of (49). Using (52), we deduce

\[
\text{LHS of (49)} \geq \sum_{t=1}^{T} \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle - G^2 (\|\alpha_0 \hat v_0^{-1/2}\|_1 - \|\alpha_T \hat v_T^{-1/2}\|_1)
\]

\[
\geq \sum_{t=1}^{T} \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle - \alpha G^2 \|\hat v_0^{-1/2}\|_1, \tag{58}
\]

where we used \( \alpha_0 = \alpha \) and \( \|\alpha_T \hat v_T^{-1/2}\|_1 \geq 0 \).

Finally, combining (57), (58), and (49), we arrive at

\[
\sum_{t=1}^{T} \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle \leq f(x_1) - f(x_*) + \frac{\alpha \beta_1 G^2}{1 - \beta_1} \|\hat v_0^{-1/2}\|_1 + \alpha G^2 \|\hat v_0^{-1/2}\|_1
\]

\[
+ \frac{\beta_1 G^2 d}{4(1 - \beta_1) L} + \frac{d L \alpha^2 (1 - \beta_1)(1 + \log T)}{(1 - \beta_2)(1 - \gamma)}
\]

\[
\leq f(x_1) - f(x_*) + \frac{\alpha G^2}{1 - \beta_1} \|\hat v_0^{-1/2}\|_1 + \frac{\beta_1 G^2 d}{4(1 - \beta_1) L} + \frac{d L \alpha^2 (1 - \beta_1)(1 + \log T)}{(1 - \beta_2)(1 - \gamma)}, \tag{59}
\]

where we used that \( \hat v_0^{-1/2} \geq \hat v_{1,t}^{-1/2} \).

Since \( E_T \) is conditioned on the history until selecting \( g_t \), \( \hat v_{t-1} \) does not depend on \( g_t \), \( E_T[g_t] = \nabla f(x_t) \), and \( \|\hat v_t\|_\infty \leq G^2 \), we obtain

\[
E_T \left[ \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle \right] = \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), \nabla f(x_t) \rangle = \sum_{i=1}^{d} \frac{\alpha_{t-1}}{\hat v_{t-1,i}^{1/2}} (\nabla f(x_t))_i^2 \geq \frac{\alpha}{\sqrt{T} G} \|\nabla f(x_t)\|^2.
\]

Taking the full expectation above yields

\[
E \left[ \langle \alpha_{t-1} \hat v_{t-1}^{-1/2} \nabla f(x_t), g_t \rangle \right] \geq \frac{\alpha}{\sqrt{T} G} E \left[ \|\nabla f(x_t)\|^2 \right].
\]

Thus, by taking the full expectation in (59), we deduce

\[
\frac{\alpha}{\sqrt{T} G} \sum_{t=1}^{T} E \left[ \|\nabla f(x_t)\|^2 \right] \leq f(x_1) - f(x_*) + \frac{\alpha G^2}{1 - \beta_1} \|\hat v_0^{-1/2}\|_1 + \frac{G^2 d}{4 L (1 - \beta_1)} + \frac{d L \alpha^2 (1 - \beta_1)(1 + \log T)}{(1 - \beta_2)(1 - \gamma)},
\]

from which the final bound follows immediately. \( \square \)
